HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SINGLE LAYER CVD MoS₂ FOR FLEXIBLE ELECTRONICS

Two dimensional layered semiconductors, and in particular transition metal dichalcogenides such as molybdenum disulfide (MoS₂), have recently received increasing attention due to the combination of their unique electronic properties with their atomically thin geometry. In particular, single-layer MoS₂ possesses key properties that make it especially appealing as channel material in flexible field-effect transistors: a sizable band-gap, mechanical robustness, absence of dangling bonds / chemical stability, appropriate electron mobility, compatibility with room-temperature transfer and device fabrication process-flows.

Among the numerous issues that need to be solved, two are of particular importance: (1) MoS₂ must be grown at a large-scale and at low-cost while achieving crystalline quality comparable to exfoliated layers from natural crystals, (2) MoS₂ should be associated with other flexible elements within the FETs notably high-quality flexible insulators as gate dielectrics. At the GDRI-GNT conference, we would like to present our recent contributions to these questions.

We synthesized single-layer MoS₂ by CVD and optimized the conditions to grow either large-size individual triangular domains (up to 100 μ m large) or fully-covering domains (cm² scale). Extensive characterizations allowed assessing the material quality. We then integrated this material in rigid and flexible FETs.

In parallel we studied a new class of gate dielectrics based on electro-grafted organic thin films. These robust covalent organic dielectrics are produced at room temperature and under mild conditions. The process yields uniform films of adjustable thickness (in the 4-50 nm range depending on the molecular compounds and grafting parameters). We first build transistors combining exfoliated MoS₂ as channel material with one example of such new dielectrics on rigid substrates [1]. The transistors operate at low bias (gate swing of 1.5V and V_{DS}=0.5V), exhibit steep subthreshold slope as low as 110 mV/decade and are hysteresis-free due to the hydrophobic and trap-free nature of this dielectric. Very recently, we showed, using a different organic compound, that this approach can be combined with single-layer CVD MoS₂ and integrated on flexible substrates [2].
