HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

flexible micropipette of known bending stiffness. This technique is promising for acquiring information that is currently difficult to quantify with other methods. Information such as nucleus stiffness and intracellular viscosity could be effectively evaluated.

The Experimental Study Of The Dynamics Of A Self-propelled Rod

Yasamin Mohebi

Dr, Maniya Maleki (Assistant Professor of Experimental Soft Matter, Institute for Advanced Studies in Basic Sciences, Zanjan, Iran); Yasamin Mohebi (Master student of Experimental Soft Matter, Institute for Advanced Studies in Basic Sciences, Zanjan, Iran)

The self-propelled particles have two categories: Natural self-propelled particles such as bacteria, and artificial self-propelled particles made in a laboratory. It is much easier to study artificial particles because particle motion parameters can be controlled by changing laboratory conditions. In this poster, we describe the results of experiments on an artificial self-propelled rod and we show that this artificial particle has the properties of an active particle.

Large macromolecular complexes are ubiquitous in biological media (e.g. protein complexes, membrane-bound complexes...). Specific biophysical techniques can be used to assess the interactions and structures of such complexes. Two independent systems were chosen as examples. The first one deals with the formation of protein coronas (protein/nanoparticle interactions) while the second system concerns virus encapsidation (protein/RNA interactions). Here, we can see how three techniques (isothermal titration calorimetry, cryo-electron microscopy, and small angle scattering) can be combined in order to answer fundamental questions.
